Presence of thrombus ($p = 0.0001$) was the only factor predictive of vascular complications. Only 3 (0.11%) out of the 2830 procedures were complicated by vascular complications. The rate of vascular complications was similar in both genders ($p = 0.999$), in lower limb ($p = 0.227$) and in upper limb procedures ($p = 0.095$), and did not significantly differ in bilateral procedures

($p = 0.307$). None of the patients suffered a permanent sequel. Most of the complications, including the vascular, were observed in the lower limbs. Presence of thrombus was the only predictive factor for vascular complications. DISCUSSION =====

Carotid endarterectomy was first described by Wallenberg in 1904 ([@r4]) and subsequently by Wigren ([@r5]) and Crile ([@r6]) in the United States. To our knowledge, this is the largest and most recent study in literature of the evolution of this technique over time and its place within the global scenario of carotid endarterectomy. Despite the widespread availability of carotid endarterectomy in most of the countries of the world, this procedure continues to show a low rate of occurrence. In a recent review, Cohen et al. ([@r7]) showed that, in

developed countries, this surgery is performed in approximately 2,000 patients per year and in developing countries in about 5,000 per year. In the United States, the number of procedures performed increased from approximately 3,400 in 1979 to over 28,000 in 2000 ([@r8]), but, according to data from the Society of Thoracic Surgeons, the number of procedures performed in 2008 was only over 22,000 ([@r9]). In our study, after the first three procedures performed in our department in 1992, this operation became quite common, and now, the number of carotid endarterectomy procedures performed in our service per year approaches 20,000. When we performed our first carotid endarterectomy in 1992, this was a completely exclusive surgical technique. Over the last 20 years, our practice has

evolved
